ABOUT PROJECT SAGE

The SAGE Project (Soybean Asian Germplasm Evaluation) is a farmer - private sector - public sector initiative to increase the yield and genetic diversity of U.S. soybean. The mission of the project is to identify high-yielding exotic soybean accessions for use in U.S. variety development programs. Project SAGE is a follow-up of Project SAVE (Soybean Asian Variety Evaluation). The SAVE project began in 1996 with the field evaluation of 93 modern Asian varieties at 28 U.S. locations. In 1997, the SAVE project continued with field evaluation of 108 Asian varieties tested at 34 U.S. locations. In 1998, the SAVE project was expanded to the present SAGE by including not only modern Asian varieties, but also other promising accessions in the USDA soybean germplasm collection. 127 exotic accessions were tested in project SAGE at 24 locations in 1998. 135 exotic accessions were tested in project SAGE at 22 locations in 1999. This booklet summarizes agronomic performance of the exotic accessions in the SAGE tests.

The extensive SAGE field testing program was coordinated and partially financed through grants from the United Soybean Board. Yield trials were conducted by Pioneer Hi-Bred International, Inc., Monsanto Global Seed Group, Delta & Pineland Seed Co., the USDA-ARS, and the Universities of Illinois, Maryland, Minnesota, Georgia, and Arkansas, and N.C. State University.

RATIONALE FOR THE PROJECT

Soybean breeding is a true success story in U.S. agriculture. Since World War II, soybean breeding has raised farm yields 25% and provided farmers with genetic protection for an array of important diseases. The current vitality enjoyed by the soybean industry is due largely to successes in the breeding arena. More than 40 commercial companies and public institutions now develop varieties for the 70+ million acres of U.S. soybean.

Despite the remarkable achievements of U.S. soybean breeding, it is more difficult each year to maintain a competitive edge against international producers. U.S. breeders are attempting to solve this problem. One important tactic in the U.S. breeding effort has been to diversify strategies to produce superior varieties. Breeding for disease resistance, also known as defensive breeding, is one important strategy and provides outstanding varieties with nematode, virus and other resistances. Molecular transformation, a second avenue, is the newest breeding strategy and provides economically important genes not available through conventional breeding. The Roundup Ready varieties, now widely available, result from molecular research.

A third strategy for breeding progress, known as offensive breeding, boosts yield potential in the absence of pests and weeds. This type of breeding has been very important to yield improvement in the U.S. Current research suggests that U.S. breeders now have the opportunity to enhance our offensive breeding capabilities by tapping into the reservoir of global genetic diversity that exists in soybean. The purpose of this report is to help breeders do just this. The SAGE project seeks to identify agronomically important exotic germplasm for offensive breeding purposes. Such exotic germplasm has a strong likelihood of containing novel yield genes which can raise the yield ceiling for U.S. soybean varieties. The expansion of our current offensive breeding

efforts in this way will be an important part of the competitive edge in U.S. soybean production in the future.

The origin of the current SAGE project traces to a small cooperative research program among U.S. soybean breeders which began in 1978. Continuing into the early 1990's, many public and private soybean breeders participated in an ongoing cooperative effort to test exotic germplasm lines from the USDA Soybean Germplasm Collection. Over the 15-year span of the effort, about 2,000 lines (mostly of unknown relation to U.S. varieties) were tested on limited basis in a series of field trials, and some of these accessions were identified as having relatively good yields compared to commercial varieties. The application of these initial positive results to practical breeding was limited, however, because most breeders had no experience in the breeding of exotic germplasm and were unsure of the agronomic benefits to the farmer. As a result, there was insufficient follow-up validation of the agronomic potential of these exotic materials.

Recently, the exotic germplasm lines from these cooperative trials have attracted renewed interest in the breeding sector. The reasons for the renewed interest are 1) hypotheses that novel yield genes reside in such exotic germplasm, 2) availability of new DNA technology that helps us identify yield genes from such germplasm, 3) the ability to establish molecular genetic-distance relationships between exotic germplasm and U.S. breeding stock, and 4) legal restrictions on the use of elite breeding germplasm as parental breeding stock. The present SAGE test was initiated to confirm the agronomic and genetic potential of the promising germplasm lines identified through these earlier cooperative yield trials. The specific objectives of the SAGE project were to evaluate, in multi-location trials, the best lines identified in the above-mentioned cooperative tests of exotic germplasm, to collect data on yield, seed composition, and other useful agronomic traits, to compare the performance of these lines with the best available U.S. and Asian varieties, and to characterize each line with SSR markers to estimate the genetic relationships among the exotic germplasm and U.S. modern and ancestral varieties. The agronomic and seed composition data are presented in this publication.

SUMMARY OF RESULTS

OVERVIEW. Through the SAGE project, 135 exotic accessions were tested under U.S. growing conditions. Field evaluations were accomplished by organizing the accessions into a series of yield trials based on their maturity. A two-year summary of the most promising 44 exotic accessions is provided in Table 1. A detailed morphological description, a summary of agronomic performance, and a seed composition profile can be found for each entry by referring to Table 2 and the Table of Contents. Table 2 lists all 135 USDA accessions tested in SAGE in 1999 and provides the names of the tests in which they appeared. Entries in Table 2 are arranged in ascending order by Forage Crop (FC) or Plant Introduction (PI) number. More detailed information about each accession can be obtained from the National Plant Germplasm System (NPGS) GRIN (Germplasm Resources Information Network) website at <http://www.ars-grin.gov/npgs/>. To search for details about a specific accession, go to http://www.ars-grin.gov/npgs/acc/acc_queries.html and enter the Plant Introduction number you wish to learn more about (make sure to put a space between PI and the number, ex: PI 416937).

Averaged over two years, 2 exotic varieties yielded at least 90% of U.S. checks (1 Nepalese and 1 Chinese). Twenty-three exotic varieties (9 Chinese, 8 South Korean, 1 Nepalese, 1 South African, 1 Japanese, 1 Zambian, 1 Hungarian, and 1 Romanian) yielded at least 80% of the U.S. checks over years. Thirteen exotic varieties yielded at least 80% of U.S. checks in each year of the test as well as in the two-year average. Certain Japanese and Chinese varieties that performed well in the project SAVE trials (the predecessor to project SAVE) were also included in the SAVE tests as a bridge between the yield results for the two tests. Six of these thirteen yielded at least 80% of U.S. checks in at least one year of the SAGE trials, indicating that was a fair degree of agreement between the two sets of yield trials. The seven varieties from project SAVE which did not perform as well in project SAGE were almost exclusively from Japan and from maturity groups IV and later. These Japanese varieties are susceptible to bacterial pustule disease and, although ratings were not recorded, the bacterial pustule pressure may have been greater during the two years of the SAGE tests (1988 and 1999) than during the SAVE trials (1996 and 1997).

These newly identified accessions appear very promising as breeding stock for U.S. variety development. It is our hope that U.S. breeders will give these new genetic resources serious attention. Only one variety in these tests (Fen Dou 31 from China) is known to have U.S. pedigree. The other varieties from China and Japan are believed to have no common recorded ancestor with U.S. cultivars. Three Chinese cultivars which yielded greater than 80% of the U.S. checks were collected circa 1930 and, thus, predate modern breeding (PI 88310, PI 88295, and PI 91142). The variety from South Africa, which yielded greater than 80% of U.S. checks, appears unrelated to U.S. cultivars because it is susceptible to bacterial pustule, late maturing, and was collected by 1963 (PI 221717). Six of the seven South Korean varieties yielding at least 80% of U.S. checks appear unrelated to U.S. cultivars because they are small seeded and/or susceptible to bacterial pustule, late maturing, and collected before 1975. The variety from Nepal has some susceptibility to bacterial pustule and, thus, may not be closely related to U.S. varieties (PI 417931). The varieties from Europe and Zambia are more difficult to distinguish from U.S. cultivars, phenotypically, and may be more likely to trace their origins to North American breeding programs. Follow-up DNA marker studies may determine the true genetic distinction among these latter types and U.S cultivars.

All accessions reported here are freely available for hybridization from the USDA-ARS Soybean Germplasm Collection and may be obtained by request from Randall Nelson *via* email at rlnelson@uiuc.edu or *via* FAX at 217-333-4639.

METHODS

Entries, Tests, And Locations. In 1999 a total of 135 soybean accessions were evaluated from China, Japan, Egypt, Nepal, France, Hungary, Romania, Yugoslavia, Russia, South Korea, U.S., Morocco, India, South Africa, and Zambia. These 135 included the 127 which were evaluated in 1998 and 8 additional accessions in 1999. The accessions were divided into five tests and compared to elite public and private U.S. varieties. The five tests were named Test 1, Test 2, Test 3, Test 5 and Test 6 where the digit in the name refers to the approximate maturity group of the materials in the test. For example, Test 1 contains varieties predominantly of maturity group I and earlier.

Yield trials took place at 22 sites during 1999 in Minnesota, Wisconsin, Illinois, Iowa, Ohio, Maryland, Arkansas, Mississippi, North Carolina, and Georgia. Twenty-four sites were employed in 1998. At least five locations were grown for each test with two replications per test. However, some sites were lost due to flooding or drought. Please see Table 3 for a complete list of locations in 1999. Please see the 1998 SAGE book for locations in 1998. Yield and other agronomic characteristics are presented as LSMeans (least squares means) rather than simple arithmetic means, to account for occasional missing data. When a variety has no missing data in the trials, the LSMean and the arithmetic mean are identical.

Strain Designation. All accessions were identified by the Forage Crop (FC) or Plant Introduction (PI) number assigned by the USDA-ARS. Where possible, we also identified the accession by its common name. Pioneer varieties are identified by a four-digit number beginning with the number 9. Public varieties generally are named, rather than numbered, with the exceptions of IA2021 and KS4694.

Plot Size. The row spacing and number of rows per plot are listed in Table 3. In most locations the yield trials were planted in 30-inch rows, planting four rows and harvesting the two central ones. Normal local cultural practices were followed.

STATISTICAL ANALYSIS

Each individual trial was planted as a randomized complete block design with two replications. Each trial was analyzed separately and then combined across locations using SAS (SAS Institute Inc., 1985. SAS user's guide: Statistics version 6 edition. Cary, NC. 956 pp.). Variety means are reported as adjusted means from the LSMeans option of SAS, to account for occasional missing values. Although all individual trials are reported, certain trials were excluded from the combined analysis if they exhibited exceptionally low yields, exceptionally high coefficient of variation, or, in rare cases, could not be harvested prior to widespread shattering. Details are added to the tables as footnotes. At least three locations were employed for each test.

TRAITS RECORDED

Flower and pubescence color. Recorded for each variety at all locations for quality assurance. See table footnotes for abbreviations.

Maturity date. Earliest date (September 1=1) at which 95% of the pods had a mature pod color.

Height. Reported as the distance from the ground to stem tip at maturity in inches based on the mean of three plants per plot for all plots.

Lodging. Reported on a scale from 1 to 5: 1=completely erect, 5= completely prostrate.

Shattering score. Taken at 7 to 10 days after harvest unless otherwise indicated, employing a scale from 0 to 9 as follows: 0=none, 5= 40-50%, 9= 80-90% of pods in a plot shattered. Thus, shattering scores reported here did not affect yield estimates. For any plot where shattering may have occurred prior to harvest, the yield value was discarded.

Yield. Reported as bushels per acre based upon plots that were end trimmed at maturity.

100-seed weight. Reported as grams per 100 seeds.

Stem Termination. Reported as determinate (D), indeterminate (N), or semideterminate (S).

Mottling Score. Defined on a 100 seed sample basis, as the percentage of the total seed coat surface with dark pigment: 1=none, 2=1-10%, 3=10-25%, 4=25-50%, 5>50%.

Seed Quality. Scale based on disease/rotten, wrinkled or otherwise defective seed coat, and greenish color: 1=good seed, 5=poor.

Protein, oil and fatty acids composition. In 1998 and 1999, these characteristics were evaluated in two locations per test and one rep per location. Seed protein and oil were determined at 0% moisture level by near infrared reflectance (NIR), using an Infratec 1225 NR whole-grain analyzer (NIR Systems, Inc., Silver Spring, MD). Pioneer Hi-Bred International, Inc. graciously performed the oil, protein, and fatty acid evaluations.

Podwall and hilum color: Used to assure the identity of genotypes and provided by R.L. Nelson. See footnotes in each test for color abbreviations.

Table 1. Overall summary of the most promising exotic accessions from project SAGE averaged over two years. This table includes all exotic accessions that yielded at least 80% of the U.S. checks of similar maturity in at least one year of the study. Results are compiled from 5 separate tests grown at a minimum of 3 locations per test in each year. For additional agronomic data refer to individual yield trial summaries listed in Table of Contents. You may also refer to the USDA-ARS GRIN (Germplasm Resources Information Network) website for more information on any accession at: http://www.ars-grin.gov/npgs/acc/acc_queries.html.

1) Names are not available for all germplasm tested in SAGE. Duplicate names are probably samples that were collected at different times by different people.

2) Maturity Group.

3) Name of the SAGE Test in which the PI appeared in 1999.

4) Code Number for this entry in the individual SAGE tests.

5) Yield as Percent of Check(s) was calculated by dividing accession yield by the yield of the appropriate check (or checks averaged together).

6) This entry was added to SAGE tests in 1999, therefore it was not rated in 1998 and does not have a two-year average.

Table 2. List of all the accessions included in SAGE tests in 1999. Accessions are ordered by their FC (Field Crop) or PI (Plant Introduction) number. For more information regarding these accessions see the USDA-ARS GRIN (Germplasm Resources Information Network) website at <http://www.ars-grin.gov/npgs/>.

^{1]} SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 6 edition. Cary, NC. 956 pp.

^{2]} 16:0=Palmitic acid; 18:0=Stearic acid; 18:1=Oleic acid; 18:2=Linoleic acid; 18:3=Linolenic acid.

^{3]} Total of saturated fatty acids (16:0 + 18:0).

^{4]} Means for this table were obtained through computer analysis of the raw data for each trait. Means were then rounded off to the nearest tenth of a percent. As a result of round off procedures, the percentages of fatty acids may not sum to 100.0 exactly. Similarly, the values in the 16:0 and 18:0 columns may not sum to the values in the Total Sats. Column exactly.

²⁾ Maturity group assigned by USDA Soybean Germplasm Collection.

³⁾ Yield averaged over 1998 and 1999.

⁴⁾ Yield as Percent of Check(s) was calculated by dividing accession yield by the yield of the appropriate check (or checks averaged together).

⁵⁾ These accessions were only evaluated in 1999.

Table 14. Two-year summary (1998 and 1999) of overall agronomic performance of Asian soybean varieties in the SAGE Test 1 (primarily maturity group I and earlier). Means are presented as LSMeans from the GLM procedure of SAS ¹⁾. Only traits that were recorded in both years are reported here.

¹⁾ 16:0=Palmitic acid; 18:0=Stearic acid; 18:1=Oleic acid; 18:2=Linoleic acid; 18:3=Linolenic acid.

²⁾ Total of saturated fatty acids (16:0 + 18:0).

³⁾ This accession was added to the study in 1999.

⁴⁾ Means for this table were obtained through computer analysis of the raw data for each trait. Means were then rounded off to the nearest tenth of a percent. As a result of round off procedures, the percentages of fatty acids may not sum to 100.0 exactly. Similarly, the values in the 16:0 and 18:0 columns may not sum to the values in the Total Sats. Column exactly.

¹⁾ SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 5 edition. Cary, NC. 956 pp.

²⁾ Five locations were used in calculating the yield LSMeans, see individual location tables for the rest of the traits.

³⁾ 1=best, 5=worst.

⁴⁾ 0=none; 9=80-90% shattering. Shattering occurred after harvest and thus, did not affect yield results.

Table 18. Seed protein, oil and fatty acid analysis of exotic soybean varieties in the SAGE Test 2 (primarily maturity group II) evaluated in 1999. Individual values are the average of 3 locations (one replication per location) and reported as LSMeans from the GLM procedure of SAS ¹⁾.

¹⁾ SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 6 edition. Cary, NC. 956 pp.

²⁾ 16:0=Palmitic acid; 18:0=Stearic acid; 18:1=Oleic acid; 18:2=Linoleic acid; 18:3=Linolenic acid.

³⁾ Total of saturated fatty acids (16:0 + 18:0).

⁴⁾ Means for this table were obtained through computer analysis of the raw data for each trait. Means were then rounded off to the nearest tenth of a percent. As a result of round off procedures, the percentages of fatty acids may not sum to 100.0 exactly. Similarly, the values in the 16:0 and 18:0 columns may not sum to the values in the Total Sats. Column exactly.

TEST 2

(Primarily maturity group II)

INDIVIDUAL LOCATIONS IN 1999

Table 19. Yield (bu/a) of soybean accessions in SAGE Test 2 (primarily maturity group II) evaluated in 1999. Means are presented as LSMeans from the GLM procedure of SAS ¹⁾.

¹⁾ SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 6 edition. Cary, NC. 956 pp.

²⁾ Maturity group assigned by USDA Soybean Germplasm Collection.

³⁾ Yield averaged over 1998 and 1999.

⁴⁾ Yield as Percent of Check(s) was calculated by dividing accession yield by the yield of the appropriate check (or checks averaged together).

⁵⁾ Not Rated due to early maturity- no checks to compare against.

⁶⁾ This accessions was only evaluated in 1999.

Table 27. Two-year summary (1998 and 1999) of overall agronomic performance of Asian soybean varieties in the SAGE Test 2 (primarily maturity group II). Means are presented as LSMeans from the GLM procedure of SAS ¹⁾. Only traits that were recorded in both years are reported here.

¹⁾ 16:0=Palmitic acid; 18:0=Stearic acid; 18:1=Oleic acid; 18:2=Linoleic acid; 18:3=Linolenic acid.

²⁾ Total of saturated fatty acids (16:0 + 18:0).

³⁾ This accession was added to the study in 1999.

⁴⁾ Means for this table were obtained through computer analysis of the raw data for each trait. Means were then rounded off to the nearest tenth of a percent. As a result of round off procedures, the percentages of fatty acids may not sum to 100.0 exactly. Similarly, the values in the 16:0 and 18:0 columns may not sum to the values in the Total Sats. Column exactly.

¹⁾ SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 6 edition. Cary, NC. 956 pp.

²⁾ 16:0=Palmitic acid; 18:0=Stearic acid; 18:1=Oleic acid; 18:2=Linoleic acid; 18:3=Linolenic acid.

³⁾ Total of saturated fatty acids (16:0 + 18:0).

⁴⁾ Means for this table were obtained through computer analysis of the raw data for each trait. Means were then rounded off to the nearest tenth of a percent. As a result of round off procedures, the percentages of fatty acids may not sum to 100.0 exactly. Similarly, the values in the 16:0 and 18:0 columns may not sum to the values in the Total Sats. Column exactly.

TEST 3

(Primarily maturity group III and IV)

INDIVIDUAL LOCATIONS IN 1999

Table 32. Yield (bu/a) of soybean accessions in SAGE Test 3 (primarily maturity groups III and IV) evaluated in 1999. Means are presented as LSMeans from the GLM procedure of SAS ¹⁾.

^{1]} SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 6 edition. Cary, NC. 956 pp.

^{2]} Maturity group assigned by USDA Soybean Germplasm Collection.

^{3]} Yield averaged over 1998 and 1999.

^{4]} Yield as Percent of Check(s) was calculated by dividing accession yield by the yield of the appropriate check (or checks averaged together).

^{5]} Not Rated due to early maturity- no checks to compare against.

^{6]} These accessions were only evaluated in 1999.

Table 38. Two-year summary (1998 and 1999) of overall agronomic performance of Asian soybean varieties in the SAGE Test 3 (primarily maturity groups III and IV). Means are presented as LSMeans from the GLM procedure of SAS ¹⁾. Only traits that were recorded in both years are reported here.

¹⁾ 16:0=Palmitic acid; 18:0=Stearic acid; 18:1=Oleic acid; 18:2=Linoleic acid; 18:3=Linolenic acid.

²⁾ Total of saturated fatty acids (16:0 + 18:0).

³⁾ This accession was added to the study in 1999.

⁴⁾ Means for this table were obtained through computer analysis of the raw data for each trait. Means were then rounded off to the nearest tenth of a percent. As a result of round off procedures, the percentages of fatty acids may not sum to 100.0 exactly. Similarly, the values in the 16:0 and 18:0 columns may not sum to the values in the Total Sats. Column exactly.

LSMEAN		33.3	53	28	2.4	14.3	2.3

¹⁾ SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 5 edition. Cary, NC. 956 pp.

²⁾ Three locations were used in calculating the yield LSMeans, see individual location tables for the rest of the traits.

³⁾ 1=best, 5=worst.

⁴⁾ 0=none; 9=80-90% shattering. Shattering occurred after harvest and thus, did not affect yield results.

Table 42. Seed protein, oil and fatty acid analysis of exotic soybean varieties in the SAGE Test 5 (primarily maturity group IV and V) evaluated in 1999. Individual values are the average of 3 locations (one replication per location) and reported as LSMeans from the GLM procedure of SAS ¹⁾.

¹⁾ SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 6 edition. Cary, NC. 956 pp.

²⁾ 16:0=Palmitic acid; 18:0=Stearic acid; 18:1=Oleic acid; 18:2=Linoleic acid; 18:3=Linolenic acid.

³⁾ Total of saturated fatty acids (16:0 + 18:0).

⁴⁾ Means for this table were obtained through computer analysis of the raw data for each trait. Means were then rounded off to the nearest tenth of a percent. As a result of round off procedures, the percentages of fatty acids may not sum to 100.0 exactly. Similarly, the values in the 16:0 and 18:0 columns may not sum to the values in the Total Sats. Column exactly.

TEST 5

(Primarily maturity group IV and V)

INDIVIDUAL LOCATIONS IN 1999

Table 43. Yield (bu/a) of soybean accessions in SAGE Test 5 (primarily maturity groups IV and V) evaluated in 1999. Means are presented as LSMeans from the GLM procedure of SAS ¹⁾.

¹⁾ SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 6 edition. Cary, NC. 956 pp.

²⁾ Maturity group assigned by USDA Soybean Germplasm Collection.

³⁾ Yield averaged over 1998 and 1999.

⁴⁾ Yield as Percent of Check(s) was calculated by dividing accession yield by the yield of the appropriate check (or checks averaged together).

Table 50. Two-year summary (1998 and 1999) of overall agronomic performance of Asian soybean varieties in the SAGE Test 5 (primarily maturity groups IV and V). Means are presented as LSMeans from the GLM procedure of SAS ¹⁾. Only traits that were recorded in both years are reported here.

Code	PI Number	Yield (bu/a) ²⁾	Maturity (Sept 1=1)	Plant Height (in)	Lodging (1 to 5) ³⁾	Shattering (0 to 9) ⁴⁾	100-Seed Weight (g)

LSMean		34.3	43	27	2.4	2.0	14.8

¹⁾ SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 5 edition. Cary, NC. 956 pp.

²⁾ Three locations were used in calculating the yield LSMean, see individual location tables for the rest of the traits.

³⁾ 1=best, 5=worst.

⁴⁾ 0=none; 9=80-90% shattering. Shattering occurred after harvest and thus, did not affect yield results.

Table 51. Two-year summary (1998 and 1999) of seed protein, oil and fatty acid analysis of exotic soybean varieties in the SAGE Test 5 (primarily maturity group IV and V).

LSMEAN		19.1	44.1	11.1	3.8	23.5	54.6	7.0	14.9

¹⁾ 16:0=Palmitic acid; 18:0=Stearic acid; 18:1=Oleic acid; 18:2=Linoleic acid; 18:3=Linolenic acid.

²⁾ Total of saturated fatty acids (16:0 + 18:0).

³⁾ Means for this table were obtained through computer analysis of the raw data for each trait. Means were then rounded off to the nearest tenth of a percent. As a result of round off procedures, the percentages of fatty acids may not sum to 100.0 exactly. Similarly, the values in the 16:0 and 18:0 columns may not sum to the values in the Total Sats. Column exactly.

²⁾ 16:0=Palmitic acid; 18:0=Stearic acid; 18:1=Oleic acid; 18:2=Linoleic acid; 18:3=Linolenic acid.

³⁾ Total of saturated fatty acids (16:0 + 18:0).

⁴⁾ Means for this table were obtained through computer analysis of the raw data for each trait. Means were then rounded off to the nearest tenth of a percent. As a result of round off procedures, the percentages of fatty acids may not sum to 100.0 exactly. Similarly, the values in the 16:0 and 18:0 columns may not sum to the values in the Total Sats. Column exactly.

¹⁾ SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 6 edition. Cary, NC. 956 pp.

²⁾ Maturity group assigned by USDA Soybean Germplasm Collection.

³⁾ Yield averaged over 1998 and 1999.

⁴⁾ Yield as Percent of Check(s) was calculated by dividing accession yield by the yield of the appropriate check (or checks averaged together).

Table 63. Two-year summary (1998 and 1999) of overall agronomic performance of Asian soybean varieties in the SAGE Test 6 (primarily maturity groups V and later). Means are presented as LSMeans from the GLM procedure of SAS ¹⁾. Only traits that were recorded in both years are reported here.

Code	PI Number	Yield (bu/a) ²⁾	Maturity (Sept 1=1)	Plant Height (in)	Lodging (1 to 5) ³⁾	100-Seed Weight (g)	Shattering (0 to 9) ⁴⁾

LSMean		31.4	39	32	2.4	15.4	1.8

¹⁾ SAS Institute Inc. 1985. SAS user's guide: Statistics, Version 5 edition. Cary, NC. 956 pp.

²⁾ Four locations were used in calculating the yield LSMeans, see individual location tables for the rest of the traits.

³⁾ 1=best, 5=worst.

⁴⁾ 0=none; 9=80-90% shattering. Shattering occurred after harvest and thus, did not affect yield results.

Table 64. Two-year summary (1998 and 1999) of seed protein, oil and fatty acid analysis of exotic soybean varieties in the SAGE Test 6 (primarily maturity group VI and later).

CODE	Entry	Oil	Pro	Fatty Acid Composition ^{1) 3)}					Total Sats. ²⁾
				16:0	18:0	18:1	18:2	18:3

LSMEAN		19.4	44.0	10.8	4.0	24.8	53.8	6.5	14.8

¹⁾ 16:0=Palmitic acid; 18:0=Stearic acid; 18:1=Oleic acid; 18:2=Linoleic acid; 18:3=Linolenic acid.

²⁾ Total of saturated fatty acids (16:0 + 18:0).

³⁾ Means for this table were obtained through computer analysis of the raw data for each trait. Means were then rounded off to the nearest tenth of a percent. As a result of round off procedures, the percentages of fatty acids may not sum to 100.0 exactly. Similarly, the values in the 16:0 and 18:0 columns may not sum to the values in the Total Sats. Column exactly.

ERRATA

(Corrections to SAGE 1998 Book)

Many thanks to Dr. Elroy Cober (Agriculture and Agri-Food Canada) for noticing the errors in SAGE 1998 Test 1 summary and alerting us to the problem.

Correction #1. Correction for SAGE 1998 Test 1 Tables 5, and 7 through 12. The names of entries 7 through 11 were accidentally pasted over the names of entries 6 through 10. Table 65 depicts the tables as they appeared in the 1998 SAGE book on the left and how they should look when corrected on the right.

1998 SAGE Book Test 1		
	Uncorrected	Corrected
Code	PI Number	PI Number
1	9171	9171
2	Lambert	Lambert
3	Parker	Parker
4	PI511866	PI511866
5	PI592919	PI592919
6	PI592923	PI592921
7	PI593972	PI592923
8	PI088295	PI593972
9	PI361066A	PI088295
10	PI361075	PI361066A
11	PI361075	PI361075
12	PI391583	PI391583
13	PI391594	PI391594
14	PI407710	PI407710
15	PI424195B	PI424195B
16	PI427099	PI427099
17	PI436682	PI436682
18	PI445830	PI445830
19	PI445837	PI445837

Correction #2. Correction to Table 1 in SAGE 1998 book. Three of the errors in the entry names shown above in Correction #1, also appear in Table 1 of the SAGE 1998 Book. Corrections appear below.

Incorrect PI Number	Corrected PI Number	Correct Accession Name	Country of Origin	MG	SAGE Test Name	Yield (bu/ac)	Yield as Percent of Check(s)
PI592923 ^{1]}	PI592921	Hei nong No. 37	China	I	1	51	88
PI361066A ^{2]}	PI088295		Yugoslavia	I	1	48	82
PI088295	PI593972	Suzumaru	Japan	I	1	47	81

^{1]} PI592923 actual yield of 36 (bu/ac), which was 70% of appropriate checks.

^{2]} PI361066A actual yield of 45 (bu/ac), which was 77% of appropriate checks.

This project was supported by the

UNITED SOYBEAN BOARD

(USB Project 9211)

in cooperation with the

USDA-ARS

and other agencies listed on the cover of this document.

All accessions reported here are freely available for hybridization from the USDA-ARS Soybean Germplasm Collection and may be obtained by request from Randall Nelson *via* email at rlnelson@uiuc.edu or *via* FAX at 217-333-4639.
